Abstract: Cervical carcinoma is the second most common malignancy of genital tract. Risk factors include early age at first intercourse, smoking and multiple sexual partners. Cervical cancer can be prevented by Pap smear screening test. Pap smear is still an underutilized diagnostic modality in under developed countries. Provision and appropriate treatment should be offered in female. Objective of this study was to address the mindset of our females about pap smear screening and spreading awareness. This descriptive study was done in Obstetrics and Gynecology department of Sharif Medical City Hospital Lahore from January 2017 to January 2018 on 180 patients. Age, parity and duration of marriage were expressed as mean and frequency with percentages. Reasons of acceptance and decline were also expressed as frequency with percentage. The age range of the patient in present study was between 18-62±8.565 years. Regarding marital status, all the recruited females were married. Parity range was from 0-9±2.101 with a mean parity of 3.03. There were 129 females who accepted Pap smear. The most frequent reason for acceptance was recommendation by doctor in 93 (72%) patients. Out of 180 patients, 51 patients were those who decline Pap smear. The reason of decline was fear of pain in 17 (33.3%) patients, fear of a positive result and lack of knowledge. Cervical cancer is a deadly disease which affects the females in their early reproductive year. Screening should be offered in all reproductive females and it should be promoted through media campaigns. It is the responsibility of doctors as well to offer this screening test to all the female coming with or without gynecological complaints.

Keywords: Pap Smear, Cervical Carcinoma, Human Papilloma Virus, Risk Factors

1. Introduction

Cervical carcinoma is the second most common malignancy of genital tract. Cervical cancer is caused by human papilloma virus type 16 and 18 which is a sexually transmitted infection. Risk factors include early age at first intercourse, smoking and multiple sexual partners [1]. Throughout the world 493,000 new cases are reported annually and 274,000 death due to cervical carcinoma. In underdeveloped countries, 83% cases are reported of cervical carcinoma making an annual death rate of 15% [2]. In 2008, national cancer coalition found out that lack of effective screening programme is the main reason of high incidence of cervical cancer. In underdeveloped countries it is associated with maternal morbidity and mortality as well [3, 4]. Cervical cancer can be prevented by Pap smear screening test which is

cheap, proficient and effective test in detection of cervical abnormalities. By spreading the knowledge of cervical cancer screening, in United States there is a 2% per year decline of death due to cervical cancer. United Kingdom had also observed a decline in cervical cancer due to wide implementation of cervical screening programme. In developed countries screening is offered at 25 years with a repeat test every 3 years till 49 years and then five yearly till 64 years. But underdeveloped countries are still lagging behind and we still receive a lot of patients who are at advanced stage of disease where radiotherapy is the only hope with least survival. There is a need to increase the acceptance of Pap smear screening in our country as well, which has a proven efficacy to reduce the incidence and death due to cervical carcinoma. In a study by Gustafsson et al, 90% reduction in the incidence of cervical cancer is seen

by Pap smear screening [5]. The rate of screening by pap smear in underdeveloped countries is less than 10% [6, 7].

Lack of knowledge, lack of provision of pap smear screening programme and lack of health care facilities are the main reasons of development of carcinoma of cervix in developing countries [8]. The sensitivity of pap smear is 50-75% and specificity is 98-99% [9]. HPV infection can affect 75% of women worldwide [10]. Preventive measures needs to be adopted which include having pap smear frequently, vaccination against HPV, quit smoking and adopting safe sex practices [11, 12].

Screening of cervical cancer has been advanced. New screening programme models are introduced. Visual inspection with acetic acid (VIA) and human papilloma virus (HPV) DNA is the test which is commercially available in China and India since 2013. These tests are cheap and effective alternative to Pap smear in low resource countries. VIA has been selected by 24 countries as a national screening strategy. HPV-DNA testing has a higher sensitivity in the detection of high grade cervical lesions than Pap smear and VIA [13].

The objective of doing this study is that Pap smear is still an underutilized diagnostic modality in underdeveloped countries. We receive patients of cervical carcinoma at an advanced stage due to the lack of provision and awareness of Pap smear in our population. Cervical cancer can be detected at an early stage with the use of Pap smear and continuous follow-up of patients. Most patients are either not aware of it or don't want to get it done. So it's a need of time to spread awareness in our ladies about this disease and find out the reasons of acceptance and decline of this preventive diagnostic modality. By doing so, we can address the concerns of patients more appropriately and can use it more efficiently and effectively.

Rationale of study is that we need to address the mindset of our patients. Majority of our patients came from periphery for which the importance of this screening test is least. By doing this study we will find the reasons to address the perception and attitude of females. This will help us in increasing the acceptability of pap smear. Local studies are available but still there is need to do studies in different setups.

2. Material and Method

This descriptive study was done in obstetrics and gynecology department of Sharif Medical City Hospital Lahore from January 2017 to January 2018 on 180 patients. Ethical approval was taken from ethical committee of Sharif City Hospital. Patients were recruited from OPD by convenient sampling technique coming with gynecological or obstetrical problems. A survey Proforma was formed and all the data was entered on it by direct questioning by doctor. Sample size was calculated approximately 180 with confidence interval of 95% with acceptable difference of 0.05 and with assumed proportion of knowledge as 12.6%. All the available data was entered on SPSS version 23. Age, parity

and duration of marriage were expressed as mean and frequency with percentages. Reasons of acceptance and decline were also evaluated as frequency with percentage.

3. Results

The age range of the patient in present study was between 18-62±8.565 years as shown in table 1. Regarding marital status, all the recruited females were married with duration of marriage shown in table 2. Parity range from 0-9±2.101 with a mean parity of 3.03 (table 3). Out of 180 patients, 51 patients were those who decline pap smear (table 4). Out of 180 patients, 129 patients accepted the pap smear (table 5). The most frequent reason for acceptance was recommendation by doctor in 93 (72%) patients.

Table 1. Age in years (n=180).

Age	Frequency	Percentage
< 20 years	3	1.6%
21-25 years	22	12.2%
26-30 years	51	28.3%
31-35 years	42	23.3%
36-40 years	32	17.7%
41-45 years	13	7.2%
45-50 years	10	5.5%
>50 years	7	3.8%
Total	180	100%

Table 2. Duration of marriage (n=180).

Married for	Frequency	Percentage
1-5years	58	32.2%
6-10 years	55	30.5%
11-15 years	18	10%
16-20 years	28	15.5%
21-25 years	8	4.4%
26-30 years	10	5.5%
>30 years	3	1.6%
Total	180	100%

Table 3. Parity (n=180).

Parity	Frequency	Percentage
Nulliparous	23	12.8%
Para 1	20	11.1%
Para2-3	71	39.4%
Para 4-5	41	22.8%
>5 parity	25	14%
Total	180	100%

Table 4. Reasons of decline of cases of Pap smear (n=51).

Reasons of decline	Frequency	Percentage
Do not know about it before	5	9.8%
Fear of pain	17	33.3%
Fear of a positive result	11	21.56%
Lack of awareness about cervical cancer	1	1.96%
Lack of knowledge	7	13.7%
Anxiety/ embarrassment	2	3.92%
Financial cost	7	13.7%
Others	1	1.96%
Total	51	

Table 5. Reasons of acceptance of pap smear (n=129).

Reasons of acceptance of pap smear	Frequency	Percentage
Recommended by doctor	93	72%
Screening test	10	7.7%
Came to know by friend or relative	8	6.2%
Heard on TV/radio/social network	18	13.95%
Performed previously and now on follow up	0	0
Seen someone in family suffering from disease	0	0
Others	0	0
Total	129	100%

4. Discussion

Cervical cancer can be prevented by early detection of precancerous lesions and timely treatment. Developed countries like UK had adapted a nationwide screening programme. Underdeveloped countries like ours are still lagging behind in the implementation of these programmes at mass level. For this reason we receive patients at an advanced stage of disease, at that time the only cure is giving radiotherapy and palliative care. Moreover, Screening behaviors are also affected by the cultural and religious beliefs, barriers in communications, habits, customs and socioeconomic class as well.

The age range of the patient in present study was between 18-62±8.565 years which are comparable to a study performed in Cameroon [2].

Results of study shows that majority of females were married and residing in rural areas in a low socioeconomic class. These findings are comparable to a study performed in Brazil [12]. To our surprise, out of 180 patients who were offered screening, 129 (71%) females accepted it despite coming from a rural background. These finding are comparable to a study performed in Nigeria where awareness of population was 74.6% [1]. While decline was noted in 51 (28%) females. These findings contradict with the finding of a study done in Karachi where lack of awareness was found to be lack of information of health care provider about the disease [13].

This also highlight the importance of training of health care professionals in disseminating this information to their patients and offering pap smear in those patients who are coming with other complaints and addressing their fear as well.

Among the patients who accepted pap smear the most frequent reason was recommendation by a doctor, these finding are comparable to a study performed in China [14]. The other frequent reason was information through TV, radio and social networking which is in contrast to a study performed in Nigeria where it was found to be a most frequent source of information [1]. This reflects the importance of media contribution toward spreading awareness. None of the participants had a family member suffering from disease.

Decline was seen in 51 patients only and the most frequent reason encountered for decline was fear of pain, followed by

fear of a positive result and lack of knowledge. These finding are comparable to a study performed in Canada [15, 16]. People are not aware of sign and symptoms of disease and risk factors these findings are comparable to a study performed in Saudi Arabia [17, 18].

5. Conclusion

Cervical cancer is a deadly disease which affects the females in their early reproductive year. Detection of the disease by Pap smear of early dysplastic lesions and precancerous lesions is a option for all females. Screening should be offered in all reproductive females and it should be promoted through media campaigns. It is the responsibility of doctors as well to offer this screening test to all the female coming with or without gynecological complaints.

Based upon the results of the study following recommendations were made.

6. Recommendations

- Mass screening at government level should be offered. Awareness campaigns through media, seminars and at social and religious forums needs to be done to spread awareness in our females.
- Training of trainers i.e. the health providers need to know the importance of offering this test which can reduce the burden of disease and early diagnosis of precancerous lesions can be done.
- Public sector hospitals are offering this test free of cost or at a negligible cost, private sector hospital cost it in varying range. To eliminate the barrier of financial burden the cost needs to be kept at a minimum.
- Most of the doctor don't know what to do if a test comes positive or even have difficulty in interpretation of results. Promotion of referral system and timely referral to a dedicated centre with colposcopic services should be done. Enhancing the skill of primary care Staff should be done to deal with such patients.
- Risk factors for cervical cancer include early age at first intercourse, having multiple sexual partners and smoking. Spreading awareness about these risk factors is a beneficial step in reducing the burden of disease.
- Strengthening the system's capacity at tertiary care level for diagnostic imaging, cytology and histopathology. Provision of treatment equipment of precancerous lesions and cancer treatment should be done.
- At Government level a case registry should be maintained to establish the incidence of cervical cancer.
- Promotion of vaccination against HPV in all pre-pubertal girls and in those with high risk sexual behaviors should be offered.

- ix. Frequency of Pap smear should be according to our local protocol and systems needs to be established to provide this service to all out reach areas as well.

Limitation and Strengths of Study

Sample size of the study was small and it may not be a true representative of the whole population. Studies are needed at a larger scale with more sample size with multicentre involvement and randomized case control trials. This study, however give us overview about knowledge of cervical cancer in our females and highlight the need to do further studies.

Ethical Approval

Ethical approval was taken from hospital ethical committee.
